### ADULT Treatment Guidance for COVID-19 in the Ambulatory Setting

**Updated 12/15/2020**

**Available Therapy through Emergency Use Authorization (EUA)**

(Subject to change as more data becomes available and based on medication availability)

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Rationale for use</th>
<th>Recommendation</th>
</tr>
</thead>
</table>
| Bamlanivimab       | Inhibits viral attachment to human ACE2 receptor | Neutralizing monoclonal antibodies that bind to the spike protein of SARS-CoV-2, preventing spike protein attachment to ACE2 receptor | - EUA granted for the treatment of non-hospitalized patients with mild-moderate COVID-19 who are at high risk for disease progression.  
- Bamlanivimab reduced the need for hospitalization compared with placebo in the BLAZE-1 trial.¹  
- Casirivimab/imdevimab reduced the rates of medically attended visits (MAVs) in an ongoing randomized trial²  
- **Current YNHH criteria for approval:**  
  - Patients must be 12 years of age and older, weigh at least 40 kg, have a documented positive result of a direct SARS CoV-2 viral test within the last 7 days AND meet the following criteria listed below:  
    - A) Patients ≥ 75 years of age  
    - B) Patient less than 75 years of age AND have one of the following co-morbidities:  
      1) Chronic Kidney Disease, Stage III or higher or receiving dialysis  
      2) Congestive Heart Failure NYHA Class III or higher  
      3) Severe pulmonary disease defined as one of the following:  
         a) COPD with continuous home oxygen  
         b) Pulmonary hypertension or pulmonary fibrosis  
         c) Cystic fibrosis  
      4) One of the following hematologic/oncologic diagnoses:  
         a) S/P stem cell transplant  
         b) Active chemotherapy for acute leukemia, lymphoma, or myeloma  
      5) S/P solid organ transplant  
      6) Immunosuppressive therapy defined as:  
         a) Receiving or have received lymphocyte depleting monoclonal antibody therapy (e.g., rituximab, ofatutumab, ocrelizumab, alemtuzumab, etc.)  
      7) Parkinson’s disease  
      8) Patient aged 12-17 with one of the following:  
         a) Congenital or acquired heart disease |
b) Neurodevelopmental disorders  
c) Medical-related technological dependence, for example, tracheostomy, gastrostomy, or positive pressure ventilation (not related to COVID-19)  
d) Chronic respiratory disease excluding asthma

- **Current YNHH exclusion criteria:**
  - Hospitalized due to COVID-19
    - Monoclonal antibodies, such as bamlanivimab or casirivimab/imdesivimab, may be associated with worse clinical outcomes when administered to hospitalized patients with COVID-19 requiring high flow oxygen or mechanical ventilation.
  - OR
    - Patients who require oxygen therapy due to COVID-19 or who require an increase in baseline oxygen flow rate due to COVID-19 in those on chronic oxygen therapy due to underlying non-COVID-19 related comorbidity.

- Pregnancy and/or lactation is not a contraindication for use, however, recommended risks versus benefits are discussed with patient’s OB/GYN and/or pediatrician.

- For more information on how to refer patients for monoclonal antibody therapy, refer to Epic tools under “COVID-19 Monoclonal Antibody References” or copy and paste the following link into your browser: [https://www.ynhhs.org/patient-care/covid-19/for-employees/for-employees.aspx](https://www.ynhhs.org/patient-care/covid-19/for-employees/for-employees.aspx)
  - Scroll to Outpatient Clinical Resources and find COVID-19 Monoclonal Antibody Therapy Tips and Tricks for Referrals

</thead>
</table>
| **Anticoagulation**        | Anti-coagulants                                                                      | - There is insufficient evidence to support the use of anticoagulation for OUTPATIENTS with COVID-19  
  - Please see Appendix 1 for more information on the use of anti-coagulants in patients discharged from the hospital following admission for COVID-19 |
| **Vitamin D2 (ergocalciferol)** & **Vitamin D3 (cholecalciferol)** | Immune system modulation⁷, Lower viral replication⁸, Reduce mortality⁸, Vitamin D deficiency linked with cytokine storm biomarkers⁹-¹¹ | - There is insufficient evidence to recommend vitamin D for prevention of COVID-19  
  - Patients who require vitamin D replacement can continue or be initiated as appropriate  
  - There are no completed trials to date evaluating the use of Vitamin D for COVID-19. There are ongoing clinical trials assessing potential benefit.¹²,¹³  
  - There is conflicting evidence regarding the benefits of Vitamin D in preventing other respiratory viral infections, such as influenza. In these studies, several studies using lower doses of Vitamin D support its benefit in preventing respiratory tract infections¹³,¹⁴,¹⁵, while another showed opposite effects in pediatric patients¹⁶, and other studies showed mixed results.¹⁷ |
| **Zinc**                   | Increased intracellular concentrations of zinc impair replication in a number of RNA viruses like SARS-CoV-2 ¹⁸ | - There is no data to support the use of zinc for the prevention of COVID-19  
  - The NIH COVID-19 Treatment Guidelines recommend against using zinc supplementation above the recommended dietary allowance for the prevention of COVID-19 (11 mg daily for men and 8 mg for non-pregnant women)  
  - Retrospective data investigating the benefits of zinc supplementation was flawed as patients who received zinc had higher baseline absolute lymphocyte counts compared with those who did not receive zinc¹⁹ |
| **Vitamin C**              | Decrease inflammation and vascular injury in patients with COVID-19                  | - There is insufficient data to recommend the use of vitamin C for the prevention of COVID-19  
  - Patients who are not critically ill are less likely to experience oxidative stress or severe inflammation, so the role of vitamin C in this setting is unknown  
  - There are no completed clinical trials of vitamin C in patients with COVID-19, and the available observational data are sparse and inconclusive |
| **Famotidine & Cetirizine** | Potential inhibition of 3CL protease and of histamine-mediated cytokine storm        | - There is insufficient evidence to support the use of famotidine or combination histamine blockers to prevent COVID-19  
  - A retrospective cohort study comparing 84 patients treated with famotidine against 1536 patients not receiving famotidine concluded that famotidine may decrease the composite outcome of death or intubation (HR 0.42; 0.21 to 0.85), however the IDSA guidelines determined this to be very low level evidence given high suspicion of publication bias²⁰ |
A physician-sponsored cohort study in hospitalized patients found a reduction in the progression of symptoms with the combination of famotidine and cetirizine. However, this study is limited by study design and the number of patients not receiving dual antihistamine therapy (12 compared to 110). No published randomized controlled trial supports the use of famotidine for the prevention or treatment of COVID-19.

</table>
| Aspirin | Prevent thromboembolic events associated with COVID-19 | ▪ There is insufficient evidence to support the initiation of aspirin in non-hospitalized patients with COVID-19  
▪ Patients who take aspirin should CONTINUE TREATMENT for other underlying medical conditions unless they develop significant bleeding or other contraindications.  
▪ Sufficiently powered randomized controlled trials are needed to assess the efficacy of aspirin in patients with COVID-19 |
| Vitamin D2 (ergocalciferol) & Vitamin D3 (cholecalciferol) | Lower viral replication  
▪ Reduce mortality  
▪ Vitamin D deficiency linked with cytokine storm biomarkers | ▪ There is insufficient evidence to recommend vitamin D for the treatment of COVID-19  
▪ Patients who require vitamin D replacement can continue or be initiated as appropriate  
▪ Some recently published retrospective observational studies concluded that patients with COVID-19 had lower levels of vitamin D. While these patients may need vitamin D replacement regardless of COVID-19 prevention, further clinical trials are necessary to connect its relationship with COVID-19. |
| Zinc | Increased intracellular concentrations of zinc impair replication in a number of RNA viruses like SARS-CoV-2 | ▪ There is no data to support the use of zinc for the treatment of COVID-19  
▪ Retrospective data investigating the benefits of zinc supplementation was flawed as patients who received zinc had higher baseline absolute lymphocyte counts compared with those who did not receive zinc |
| Vitamin C | Decrease inflammation and vascular injury in patients with COVID-19 | ▪ There is insufficient data to recommend the use of vitamin C for the treatment of COVID-19  
▪ Patients who are not critically ill are less likely to experience oxidative stress or severe inflammation, so the role of vitamin C in this setting is unknown  
▪ There are no completed clinical trials of vitamin C in patients with COVID-19, and the available observational data are sparse and inconclusive |
| Famotidine & Cetirizine | Potential inhibition of 3CL protease and of histamine-mediated cytokine storm | ▪ There is insufficient evidence to support the use of famotidine or combination histamine blockers to treat COVID-19  
▪ A retrospective cohort study comparing 84 patients treated with famotidine against 1536 patients not receiving famotidine concluded that famotidine may decrease the composite outcome of death or intubation (HR 0.42; 0.21 to 0.85), however IDSA guidelines determined this to be very low level evidence given high suspicion of publication bias  
▪ No published randomized controlled trial supports the use of famotidine for the treatment of COVID-19 |
## Fluvoxamine

**SSRI**

- σ-1 receptor agonist
- Potential immune modulation via σ-1 receptor (S1R) agonism

- There is insufficient evidence to support the use of fluvoxamine for the treatment of COVID-19
- A randomized trial found a lower likelihood of clinical deterioration in adult outpatients with COVID-19 treated with fluvoxamine compared with placebo\(^{35}\), however this study had several limitations including small sample size and potential for bias given primary and secondary endpoints were measured using participants’ self-reported responses on surveys.

## Colchicine

**Anti-gout agent**

- Anti-inflammatory and anti-viral properties\(^{36}\)
- Inhibition of PMN cell migration

- There is insufficient evidence to support the use of colchicine for the treatment of COVID-19
- There is an ongoing phase III trial to evaluate the efficacy and safety of colchicine in adult outpatients diagnosed with COVID-19 infection\(^{37}\), however there is no current published data to support the use of colchicine at this time.

## Medications with Previous Safety Concerns in COVID-19

### Nonsteroidal Anti-Inflammatory Drugs (NSAIDS)

**COX-1/2 inhibition**

- Potentially increases ACE2 expression resulting in worsened COVID-19 infection
- Appropriate to use in COVID-19 patients
- Considerations for NSAID prescribing should always include evaluation of inherent NSAID side effects (i.e. risk of renal dysfunction), regardless of COVID-19 diagnosis
- No published peer reviewed studies support NSAIDs worsening COVID-19 infections.
- European Medicines Agency (EMA) and the Food and Drug Administration (FDA) issued statements that there is no scientific evidence connecting NSAID use and worsening COVID-19 symptoms\(^{38,39}\)

### Renin-Angiotensin-Aldosterone System (RAAS) Inhibitors

**ACE inhibition and ARB antagonist**

- Potentially increases ACE2 expression resulting in worsened COVID-19 infection
- RAAS antagonists should be continued for patients currently prescribed such agents for other underlying medical conditions such as heart failure, hypertension, or ischemic heart disease.
- Two recent observational studies found no association between ACEI or ARB use and COVID-19 positivity or infection-related morbidity/mortality\(^{40,41}\)
- Additionally, a retrospective multicenter study of 1128 patients with hypertension and COVID-19 admitted to 9 hospitals in Hubei, China found that ACEI/ARB use may have been associated with lower risk of all-cause mortality\(^{42}\)
Appendix 1: Recommendations on the management of anticoagulation in patients discharged from the hospital

1. Patients who had initiation of treatment doses during the hospital stay for either presumed or objectively documented venous thrombosis should be discharged on full dose anticoagulation therapy (Direct oral anticoagulant (DOAC), LMWH, warfarin) for a minimum treatment period of three months.
   - We recommend that these patients have follow up with their primary care physician or specialty physician within six weeks of discharge to assess ongoing risk benefit ratio of anticoagulation.

2. Patients who received standard dose VTE prophylaxis in hospital should not ordinarily continue with VTE prophylaxis. If, however, they are being discharged to another medical care facility, standards of care at that facility should prevail.

3. Patients who received escalated dose (intermediate dose) VTE prophylaxis could be considered for extended VTE prophylaxis with rivaroxaban 10 mg daily for 35 days or LMWH if rivaroxaban cannot be used. The following conditions can be used to determine if a patient is eligible to receive extended duration VTE prophylaxis:
   - Patient should have either:
     1. Modified IMPROVE VTE Risk Score is ≥ 4
     2. Modified IMPROVE VTE Risk Score is 2 or 3 and a D-dimer is > 2x ULN. (D-dimer measured within 24 hours of discharge should be used for this determination)
   - Patient should **NOT** have any of the following:
     1. Major bleeding during hospital stay or during the three months prior to index hospital stay
     2. Major surgery within the last four weeks
     3. Prolonged PT (INR > 1.5- measured within 24 hours of discharge)
     4. Known bleeding disorder
     5. Current use of anti-platelet therapy
     6. CrCl of < 30 mL/min
     7. Discharge platelet count < 100,000/ul (measured within 24 hours of discharge)
     8. Other contraindications to anticoagulation with a DOAC
